# PREDICTION OF PRESSURE DROP IN PACKED BED FOR WATER AND AIR SYSTEMS 

A Thesis<br>Submitted to the College of Engineering of Nahrain University in Partial Fulfillment of the Requirements for the Degree of<br>Master of Science in Chemical Engineering by<br>MARWA NADHUM ABASS<br>(B. Sc. in Chemical Engineering 2005)

Rabee Alawhal ..... 1429
March ..... 2008

## Certification

I certify that this thesis entitled "Prediction of Pressure Drop in Packed Bed for Water and Air Systems" was prepared by "Marwa Nadhum Abbas" under my supervision at Nahrain University/College of Engineering in partial fulfillment of the requirements for the degree of Master of Science in Chemical Engineering.

Signature:

Name: Dr. Mohamed N. Latif
(Supervisor)
Date: $\quad 17 / 3 / 2008$

Signature:

Date:

## Certificate

We certify, as an examining committee, that we have read this thesis entitled "Prediction of Pressure Drop in Packed Bed for Water and Air Systems", examined the student "Marwa Nadhun Abbas" in its content and found it meets the standard of thesis for the degree of Master of Science in Chemical Engineering.

Signature:

Name: Dr. Mohammed N. Latif (Supervisor)
Date: $17 / 3 / 2008$
Date: $17 / 3 / 2008$

Signature: K.S.AGoul Marin

Date: $\quad 17 / 3 / 2008$

Approval of the College of Engineering
Signature:
 Name: Prof. Dr. Muhsin J. Jweeg (Acting Dean)
Date: $13 / 4 / 203$

#### Abstract

Semi-empirical equations for fluid flow through packed bed have been proposed, depending on statistical fitting of experimental data. Two types of fluids have been used (water and air) separately (single phase flow). Several size distributions of sphere packing materials have been used in the packed bed, and each had been studied separately.

Different parameters affecting the pressure drop of fluid flow through packed bed have been studied. These parameters are fluid velocity, bed porosity, bed diameter, pore diameter, tortuosity and packing height.

A certain semi-empirical equations for fluid flow through packed bed have been proposed for a certain size and type of packing system called singular equation (mono, binary, ternary, quaternary, quinary and multi-sized spherical particle system). There were ten singular equations have been written, five of them for water flow and five for air flow through packed beds.

A general semi-empirical equation has been proposed that can be used for all types of packing systems is:

A. for air flow through packed bed.

$$
\frac{\Delta P}{L}=-5.47872 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+2.7267 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}}
$$

The average percentages errors were found $13.57423 \%$.
B. for water flow through packed bed.

$$
\frac{\Delta P}{L}=108.3983 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+2.1188 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}}
$$

The average percentages errors were found $12.9576 \%$.

The empirical formulas of pore diameter had been proposed for all the equations used in the calculations. The calculation results of these formulas have been compared with experimental results taken from documented literature data; the result equation of pore diameter for water and air is:

$$
d_{\text {pore }}=1.9612 d_{p} \varepsilon^{1.61605}
$$

The average percentages errors for air flow were found to be $0.3897 \%$, and for water flow were found to be $0.328 \%$.

## List of Contents

Contents Page
Abstract ..... I
List of Contents ..... III
Notations ..... VI
List of Tables ..... VIII
List of Figures ..... IX
Chapter One : Introduction ..... 1
Chapter Two : Literature survey
2.1 Introduction ..... 3
2.2 Packed bed ..... 5
2.3 Flow in porous medium ..... 6
2.3.1 Porosity of the bed ..... 7
2.3.2 Tortuosity factor ..... 9
2.3.3 Permeability of the bed ..... 12
2.4 Factors affected on pressure drop through packed bed ..... 13
2.4.1 Rate of fluid flow ..... 13
2.4.2 Closeness and orientation of packing ..... 16
2.4.3 The size of the particles ..... 17
2.4.4 The shape of packing ..... 18
2.4.5 The surface roughness of the particles ..... 20
2.5 Specific surface area ..... 21
2.6 Prediction of voidage distribution ..... 22
2.7 The relation between depth of the bed and pressure drop ..... 24
Chapter Three : Theoretical Aspect
3.1 Introduction ..... 25
3.2 Fluid Flow through randomly packed bed ..... 26
3.3 The tortuosirty factor ..... 33
Chapter Four : Results and discussion
4.1 The semi-empirical equations constants ..... 36
4.2 Calculation of pore diameter ..... 37
4.3 The effect of different parameters on the pressure drop ..... 39
on the proposed general equation
4.3.1 Effect of pore diameter on pressure drop ..... 40
4.3.2 Effect of porosity on pressure drop ..... 41
4.3.3 Effect of packing height on pressure drop ..... 43
4.3.4 Effect of tortuosity on pressure drop ..... 44
4.4 Comparisons between proposed equation, Ergun equation ..... 46
and experimental data.
4.4.1 Singular equations results for different sizes of ..... 46
packing.
4.4.1.1 Mono size spherical particles systems ..... 46
A. Air flow through packed bed ..... 46
B. Water flow through packed bed ..... 50
4.4.1.2 Binary sizes spherical particles systems ..... 53
A. Air flow through packed bed ..... 53
B. Water flow through packed bed ..... 56
4.4.1.3 Ternary sized spherical particles systems ..... 58
A. Air flow through packed bed ..... 58
B. Water flow through packed bed ..... 62
4.4.1.4 Quaternary sized spherical particles systems ..... 64
A. Air flow through packed bed ..... 64
B. Water flow through packed bed ..... 65
4.4.1.5 Quinary sized spherical particles systems ..... 67
A. Air flow through packed bed. ..... 67
A. Water flow through packed bed. ..... 69
4.4.2 Results of General equations for different sizes of ..... 71packing systems.

## Notations

## Symbols Notations

$\mathrm{D}_{\mathrm{b}} \quad=\quad$ Diameter of the bed (m).
$\mathrm{D}_{\mathrm{e}}=$ Effective diffusion coefficient $\left(\mathrm{m}^{2} / \mathrm{s}\right)$.
$\mathrm{D}_{0} \quad=$ Diffusion coefficient in the bulk medium $\left(\mathrm{m}^{2} / \mathrm{s}\right)$.
$\mathrm{d}_{\text {eff }}=$ Effective particles diameter (m).
$\mathrm{d}_{\mathrm{pi}}=$ Diameter of particles i in mixture (m).
$d_{p}=$ Diameter of the particle (m).
$\mathrm{d}_{\text {pore }}=$ Equivalent diameter of the pore channels (m).
$\mathrm{d}_{\mathrm{t}} \quad=\quad$ Diameter of tube (m).
$f_{w}=$ Correction factor.
$\mathrm{K}=$ Kozeny's coefficient.
$\mathrm{K}_{\mathrm{C}}=$ Kozeny's constant.
$\mathrm{K}_{1}=$ Representation of packing and fluid characteristics at laminar flow.
$\mathrm{K}_{2}=$ Representation of packing and fluid characteristics at turbulent flow
$k=$ Permeability coefficient for the bed $\left(\mathrm{m}^{2}\right)$.
$\mathrm{L} \quad=\quad$ Height of packing in the bed (m).
$\mathrm{L}_{\mathrm{e}} \quad=\quad$ Average length of porous medium (m).
$l=$ Thickness of the bed (m).
$\Delta \mathrm{p} \quad=\quad$ Pressure drop through packed bed, $\mathrm{Pa}\left(\mathrm{kg} / \mathrm{m} \cdot \mathrm{s}^{2}\right)$.
$\mathrm{R} \quad=\quad$ Reduce of horizontal pipe (m).
$\Delta \mathrm{r} \quad=\quad$ An annulus thickness of element (m).
$\mathrm{S}=$ Specific surface area of the particles $\left(\mathrm{m}^{2} / \mathrm{m}^{3}\right)$.
$\mathrm{S}_{\mathrm{B}}=$ Specific surface area of the bed $\left(\mathrm{m}^{2} / \mathrm{m}^{3}\right)$.
$\mathrm{S}_{\mathrm{c}} \quad=\quad$ Surface of the container per unit volume of the bed $\left(\mathrm{m}^{-1}\right)$.
$\mathrm{u}=$ Superficial velocity $(\mathrm{m} / \mathrm{s})$.
$\mathrm{u}_{1}=$ Average velocity through the pore channels ( $\mathrm{m} / \mathrm{s}$ ).
$\mathrm{V}_{\text {total }}=$ Total void of the bed $\left(\mathrm{m}^{3}\right)$.
$\mathrm{V}_{\text {void }}=$ Volume of the void in a bed $\left(\mathrm{m}^{3}\right)$.
$x_{i}=$ The weight fraction of particle i.

## Greek Symbols

$\varepsilon \quad=\quad$ Porosity of the bed.
$\mu=$ Fluid viscosity (kg/m.s).
$\Phi_{\mathrm{s}}=$ Sphericity.
$\rho=$ Density of the fluid $\left(\mathrm{kg} / \mathrm{m}^{3}\right)$.
$\tau \quad=$ Tortuosity factor.
$\lambda=$ orientation factor
$\alpha=$ Angle which the normal solid-liquid interface makes with the stream direction.

(4.42) Pressure drop vs. velocity for pea gravel of particles diameter 0.25 cm , pore diameter of 0.8 cm , tortuosity of 1.4506, bed porosity of 0.360902 and packing height of 8.89 cm .
(4.43) Pressure drop vs. velocity for Acrylic balls of particles diameter $\left(\mathrm{dp} 1=0.636\right.$ and $\mathrm{dp} 2=1.72 \mathrm{~cm}$, with $\mathrm{dp}_{\text {eff }}=0.7257$ $\mathrm{cm})$, fraction of $\left(x_{1}=0.75, x_{2}=0.25\right)$, ( with pore diameter of 0.27 cm , tortuosity of 1.4421 , bed porosity of 0.3612 , packing height of 50.8 cm and bed diameter of 8 cm .
(4.44) Pressure drop vs. velocity for spherical particles diameter ( $0.9987,0.7955$ and 0.509 cm , with $\mathrm{dp}_{\text {eff }}=0.647 \mathrm{~cm}$ ), pore diameter of 0.28 cm , tortuosity of 1.4349 , bed porosity of 0.3921 , packing height of 15.15 cm and bed diameter of 7.62 cm .
(4.45) Pressure drop vs. velocity for spherical particles diameter of ( $0.42,0.51,0.61$ and 1.01 cm , , with $\mathrm{dp}_{\mathrm{eff}}=0.5738 \mathrm{~cm}$ ), pore diameter of 0.23 cm , tortuosity of 1.4395 , bed porosity of 0.3719 , packing height of 15.15 cm and bed diameter of 7.62 cm .
(4.46) Pressure drop vs. velocity for spherical particles diameter of 78 ( $0.42,0.51,0.61,0.79$ and 1.01 cm , with $\mathrm{dp}_{\mathrm{eff}}=0.61 \mathrm{~cm}$ ), pore diameter of 0.23 cm , tortuosity of 1.4418 , bed porosity of 0.3623 , packing height of 15.15 cm and bed diameter of 7.62 cm .

## Chapter One

## Introduction

Fluid flow through packed bed has many important applications in chemical and other process engineering fields it is commonly used in industry to contact two fluid phases, or a fluid and solid phase. This process is used for catalytic reactions, combustion, gas absorption, gas-liquid adsorption, distillation, drying, separation [1], filter bed, waste water treatment and the flow of crude oil in petroleum reservoir [2].

Packed bed usually consists of a cylindrical column containing a large number of solid particles in contact with one another or as a network of tortuous passages formed by the spaces between the particles [3]. The packing material may be glass marbles, ceramics, plastics, pea gravel, or mixtures of materials [4]. It should have a large void volume to allow flow of fluid without excessive pressure drop and it should be chemically inert to fluids being processed [5].

In the packed column the fluid is distributed as uniformly as possible from the bottom, passes through the packed material and exits at the top of the column. There are inlet and outlet pores for the fluid and two pressure nodes above and below the packing that measure the pressure drop across the column [6]. Because of the nature of packed material, a packed column can operate using strongly corrosive fluids [7].

The surface area of the packing material increasing in efficiency of packed bed. Because increase in surface area provided by these particulate materials provides a bigger reaction area for the desired operation [1]

An understanding of pressure drop across a packed column as a function of flow rate is important when determining the energy requirements to pump a fluid for any given bed [8], in order to decrease costs of the system, but also to maintain the optimal operating conditions and to maximize the product [4].

The aim of this work is to:
I. Propose a semi-empirical equation of pressure drop over the packed bed as a function of different parameters; including fluid velocity, height of packing, pore diameter, tortuosity, bed porosity, and density and viscosity of fluid. This equation proposed for spherical particles for different size distribution of the particles (mono, binary, ternary, quaternary and quinary) and two systems of fluid, water and air flowing through a packed bed.
II. Propose an empirical equation for the tortuosity of packed bed as function of the bed porosity.
III. Propose an empirical equation for pore diameter of packed bed as a function of porosity and particle diameter.

## Chapter Two

Literature Survey

### 2.1 Introductions

The study of fluid flow through the packed bed is an important issue. Chemical engineering operations commonly involve the use of packed and fluidized beds. These are devices in which a large surface area for contact between a liquid and a gas (absorption, distillation) or a solid and a gas or liquid (adsorption, catalysis) is obtained for achieving rapid mass and heat transfer [9].

For flow of one fluid, the fluid flow from the bottom, passes through the packed material and exits at the top of the column. With two fluids, liquid enters from the top of the column and flows downward, wetting the packing material. A gas enters at the bottom, and flows upward, contacting the liquid in a countercurrent fashion, initiating mass and energy transfer between the fluids [10]

The flow of fluid through porous medium composed either of irregular shaped material or of packing of regular geometrical form has attracted considerable attention from many investigators [11].

Blake-Kozeny in 1927 [12] derived an equation that correlated the pressure drop to low fluid flow rates and it is generally good for void fractions less than 0.5 and is valid only in the laminar region given by $\left(\operatorname{\rho ud}_{\mathrm{p}} /(1-\varepsilon) \mu<10\right)$.

Burke-Plummer in 1928 [12] derived an expression for change in pressure at turbulent flow resulting from kinetic energy loss and it is only valid in the turbulent region given by $\left({\rho u d_{p}}_{p} /(1-\varepsilon) \mu>1000\right.$.

Ergun in 1952 [13] studied the pressure drop for incompressible packed beds composed of uniform spherical particles. Despite this, the Ergun model has been used in situations where the particle shape was non-spherical and/or the particle size distribution was non-uniform. Ergun equation can provide the pressure drop along the length of the packed bed given a fluid velocity. Ergun found that the pressure drop over the packing length was dependent on the rate of fluid flow, the viscosity and density of the fluid, the closeness and orientation of the packing, and the size, shape and surface of the packing material. The Ergun equation was designed for fluid flow until the fluidization point.

Leva in 1959[12] predicted of pressure drop versus flow rate based on the study of single incompressible fluids through an incompressible bed of granular salts.

Harkonen in 1987 [13], Lindqvist in 1994, Lammi in 1996, Wang and Gullichsen in 1999 [10] and Lee and Bennington in 2004 [14] measured the average void fraction and flow resistance through packed columns. And found that the pressure drop of liquid through a packed bed depends on a number of factors, including the particle species and the type and size distribution of the particles.

Gibson and Ashby in 1988, Duplessis in 1994 and Richardson in 2000 [15] studies the influence of several structural parameters such as porosity,
tortuosity, surface area and pore diameter, on predicting the pressure drop through porous medium

### 2.2 Packed Bed

The flow of fluid through bed composed of stationary granular particles is a frequent occurrence in the chemical industry and therefore expressions are needed to predict pressure drop across beds due to the resistance caused by the presence of the particles [16].

Packed systems in industry may be divided into the following classes:

1. Fixed beds
a. Solid- gas system.
b. Solid- liquid system.
2. Moving beds.
3. Solid- liquid- gas system.

Typical example of solid-gas fixed-bed systems are the catalytic reactors which were used in the Fischer-Tropsch synthesis, retorting of oil Shale, roasting of ores, combustion of coal and coke in fuel beds, and blast furnace operations.

The most important solid-liquid fixed-bed applications are water filtration, flow of oil through sand strata, coal washing, and leaching [17].

Moving beds are employed in the FCC (fluidized catalytic cracking) process and others.

The Solid-liquid-gas system comprises fractionating towers, absorbers, scrubbers, and many other kinds of chemical engineering equipment [17].

### 2.3 Flows in Porous Media

Flow in porous media has received much attention in recent years because of its important role in a large variety of engineering and technical applications, such as filtration units, packed beds, and certain types of chemical reactors.

Dullien 1992 [18] Porous materials are encountered everywhere in everyday life, in technology and in nature. A material can be defined as a porous medium if the material has the following properties.

1- The material must contain relatively small spaces, called pores or voids, imbedded in the solid. The pores usually contain some fluid, such as air, water, etc., or a mixture of different fluids [18].

2- The fluids should be able to penetrate through one face of the material and emerge on the other side [18].

Building materials, such as porcelain, or various plastics, thin-walled metal rings of steel or aluminum, glass, stone, bricks, concrete, soil, or other material are examples of porous materials. All properties of porous media are influenced by the pore structure. Pore structure parameters represent average behavior of a sample containing many pores and the some important pore structure parameters are the porosity, the tortuosity and the permeability. The porosity and the tortuosity are the characteristics of a porous medium; the permeability is the mass transfer property of the porous media [18].

Analysis of pore structure and pore radius distribution is necessary in order to construct on effective model for a porous medium [19].

The models of a porous medium consist of lattice networks of cylindrical channels with distribution of radii and also of randomly packed rotund particles examples spheres as described by Iczkowski, Mason and Haynes [20].

The significant properties of porous media are:

1. Porosity which is a measure of the pore space and hence of the fluid capacity of the medium [21].
2. Tortuosity which is a measure of fluid path through bed compared with actual depth of bed [22].
3. Permeability which is a measure of ease with which fluids may traverse the medium under the influence of a driving pressure [21].

### 2.3.1 Porosity of the Bed

The porosity ( $\varepsilon$ ) is defined as the ratio of the void volume to the total volume of the bed (the volume fraction occupied by the fluid phase). Other names given the porosity include the void fraction, fractional voidage, or simply voidage [23], i.e.:

$$
\operatorname{porosity}(\varepsilon)=\frac{V_{\text {void }}}{V_{\text {total }}}
$$

Depending on the type of the porous medium, the porosity may vary from near zero to almost unity. Kaviany in 1995 suggested that the normal range of average void fraction was from 0.36 to 0.43 [24]. Measurement of porosity is made by using several techniques, such as imbibitions, mercury injection and gas injection methods to give effective porosity value [18].

The porosity is the most important property of a porous medium and it affects most of the physical properties of the medium. For a homogeneous porous medium, the porosity may be a constant. But in general, the porosity is space dependent. Each void in the porous medium is connected to more than one other pore (through pore or interconnected), connected only to one other pore (blind pore or dead end), or not connected to any other pore (closed pore or isolated) and fluid flows through the interconnected pores [18, 25]. Figure 2.1 shows the three possible kinds of pores.

Figure 2.1 Three possible kinds of pores [25]

Many investigators described the fractional void volume of a bed of solid particles and found that the packing porosity depends upon the particle size and size distribution, the particle shape and surface roughness, the method of packing, and the size of the container relative to the particle diameter [5]; Such as Fuller and Thompson in 1987 [26] studied the influence of distribution of the particle size upon the density of granular material. Moallemi in 1989, Summers in 1994 and Ismail in 2000 studied the local voidage for the mixtures
of sphere packing (mono, binary and ternary) and found that the local voidage variations in the axial, radial and angular directions [27].

The classification of pores according to size has been under discussion for many years, but in the past the terms micro pore \{pore of internal width smaller than 2 mm \}. Macro pore \{pore of internal width greater than 50 mm \}, has been applied in different ways by physical and chemists and some other scientists in an attempt to clarify this situation .Mesopores \{pore of Internal width between 2 mm and 50 mm$\}$ are especially important in the Context of adsorption [28].

### 2.3.2 Tortuosity Factor

Tortuosity is the ratio of the average pore length $\left(\mathrm{L}_{\mathrm{e}}\right)$ to the porous medium thickness $(l)$ [18].Figure 2.2 shows the effect of tortuosity in a porous medium between the average length and the bed thickness. It's classically defined as follows [29]:

$$
\begin{equation*}
\tau=\frac{L_{e}}{l} \tag{2.1}
\end{equation*}
$$

where:
$\mathrm{L}_{\mathrm{e}}=$ average length of porous medium.
$l=$ the bed thickness.

The ratio $L_{e} / l$ being the tortuosity factor and it is usually represented by $\tau$ as described by Bear in 1972 and Dullien in 1979 [31].

Figure 2.2 The effect of tortuosity in a porous medium showing the average length and the bed thickness [30]

Tortuosity is not a physical constant and depends first of all on other porous media characteristics, like porosity, pore diameter, channel shape, etc. In general, in granular packing or beds the value of tortuosity lies in the range 1.11.7 [31].

It is difficult to determine tortuosity experimentally and in general, tortuosity is calculated by using the porosity and the effective diffusion coefficient or from the Kozeny coefficient [18].

Several empirical correlations, which suggested a relationship between tortuosity and porosity, such as Maxwell in 1873, Weissberg in 1963, Comiti and Renaud in 1989 and Boudreau in 1996 [31], are shown below:

$$
\begin{array}{ll}
\tau=1.5-0.5 \varepsilon & \text { (Maxwell, 1873) } \\
\tau=1-0.5 \ln (\varepsilon) & \text { (Weissberg, 1963) } \\
\tau=1-0.41 \ln (\varepsilon) & \text { (Comiti and Rena } \tag{2.4}
\end{array}
$$

$$
\begin{equation*}
\tau=\sqrt{1-\ln \left(\varepsilon^{2}\right)} \tag{2.5}
\end{equation*}
$$

(Boudreau, 1996)
Archie in 1942 suggested most frequently relationship between tortuosity and porosity for a mixed bed of particles dependent on the methods applied for packing preparation [32], as:

$$
\begin{equation*}
\tau=\frac{1}{\varepsilon^{n}} \tag{2.6}
\end{equation*}
$$

Where n is a numerical value, and depend on the properties of the packing bed. The value of n lies in the range from 0.4 for loose packing to 0.5 for dense packing [32]. Equations all satisfy the condition $\tau=1$ for $\varepsilon=1$, and this consistent with the physical situation observed [31].

Also tortuosity can be calculated from the effective diffusion coefficient $D_{e}$, which characterizes mass transfer in porous media, it is written as [29]:

$$
\begin{equation*}
\tau=\frac{D_{\circ}}{D_{e}} \varepsilon \tag{2.7}
\end{equation*}
$$

The tortuosity may be expressed as a function of kozeny's coefficient K as [29]:

$$
\begin{equation*}
\tau=\sqrt{\frac{K}{K_{c}}} \tag{2.8}
\end{equation*}
$$

where:
$\mathrm{K}_{\mathrm{c}}$ is the kozeny's constant.
K is the kozeny's coefficient.

Sen in 1981 and Yun in 2005 [31] showed that for an isotropic medium with spherical particles the tortuosity of porous and granular media decreases with increasing bed voidage.

### 2.3.3 Permeability of the Bed

The permeability, $k$, is the measure of the flow conductance of the porous medium and it is defined by the Darcy's law and can be written by using the porosity [18] as:

$$
\begin{equation*}
k=\left(\frac{\varepsilon}{\tau}\right)^{2} \frac{\varepsilon d_{e f f}^{2}}{36(1-\varepsilon)^{2} K_{c}} \tag{2.9}
\end{equation*}
$$

The kozeny's constant, $\mathrm{K}_{\mathrm{c}}$, is dependent of the porosity for packing [18]. Figure 2.3 shows the variation of Kozeny's constant with porosity for different shaped particles [16].

Figure 2.3 Variation of Kozeny's constant with porosity for different shaped particles [16].

The permeability is independent of the nature of the fluid but it depends on the geometry of the porous medium. The size of pore space and interconnectivity of the spaces help determine permeability [18]. Generally, the permeability of metal foam increases as the cell size increases for fixed porosity. Paek, Kang, Kim and Hyun in 2000 [33] found that for different flow velocity, pressure drop were minimum at the same solid fraction $(1-\varepsilon)$. This indicates that the pressure drop depends on the solid fraction.

### 2.4 Factors Affecting Pressure Drop through Packed Bed

The flow of single phase through a packed bed is extensively used for many chemical engineering applications, particularly for the design of fixed catalytic beds. Therefore expressions are needed to predict pressure drop across beds [34]. There are several factors affecting the pressure drop, some of them related to the physical properties of fluid such as viscosity and density, and others consists the rate of fluid flow, closeness and orientation of packing, size, shape and surface roughness of particles [4].

### 2.4.1 Rate of Fluid Flow

The flow rate of fluid is an important factor affecting the pressure drop through packed bed. When there is no flow through the packed bed, the net gravitational force acts downward. When fluid flows upwards, friction forces act upward and counter balance the net gravitational force [35]. For a high enough fluid velocity, the friction force is large enough to lift the particles. With increasing fluid velocity, the pressure drop through the bed rises until it reaches the weight of the packing per unit area. At this point, the bed starts to expand until it reaches the point of fluidization [7].

In a fixed bed, the particles are in direct contact with each other, supporting each other's weight. In an expanded bed, the particles are not in direct contact and are supported by the drag force of the fluid [36]. Figure 2.4 shows pressure drop verses velocity.

Figure 2.4 Pressure drop versus velocity. At $v_{\text {om }}$, the bed fluidizes [36].

Different crystal structures (dense or loose packing) have different void fractions. The dense packing being when the arrangement of particles; face centered cubic and hexagonal close packed. The ideal void fraction for these forms of packing is 0.26 and 0.31 respectively [36]. Figure 2.5 and 2.6 shows arrangement of sphere particles in the bed.

Figure 2.5 Hexagonal close packing [36]

Figure 2.6 Face centered cubic [37]

Carman and Kozeny [4] found that for viscous flow, the change in pressure was proportional to $(1-\varepsilon)^{2} / \varepsilon^{3}$, and derived an expression for pressure under viscous flow as:

$$
\begin{equation*}
\frac{\Delta p}{L}=\frac{150(1-\varepsilon)^{2} u \mu}{\varepsilon^{3} \phi_{s}^{2} d_{p}^{2}} \tag{2.10}
\end{equation*}
$$

At the same time, Burke and Plummer [4] discovered that the change in pressure at turbulent flow, resulting from kinematic energy loss, is proportional to $(1-\varepsilon) / \varepsilon^{3}$, and derived an expression for change in pressure at turbulent flow as:

$$
\begin{equation*}
\frac{\Delta p}{L}=\frac{1.75(1-\varepsilon) \rho u^{2}}{\varepsilon^{3} \phi_{s} d_{p}} \tag{2.11}
\end{equation*}
$$

### 2.4.2 Closeness and Orientation of Packing

It is apparent that the orientation of the particles composing the bed with respect to the direction of flow has a significant effect which depends on the shape and the arrangement of the particles. Coulson and Gupta in 1938 reported that for the same porosity, the resistance to flow changes with the arrangement of the particles relative to each other [38].

Sullivan and Hertel in 1940 [38] suggested a factor for the orientation and the equation for flow through a packed bed including this factor is:

$$
\begin{equation*}
\lambda=\left(\sin ^{2} \alpha\right) \tag{2.12}
\end{equation*}
$$

where:
$\lambda$ is the orientation factor
$\alpha$ is the angle which the normal to the solid-liquid interface makes with the stream direction.

They presented data for three specific packing; sphere, cylinders perpendicular to the direction of flow and cylinders parallel to the direction of flow. In the case of the spheres, the orientation factor equals $2 / 3$, for cylinders perpendicular to the direction of flow, the factor equals $1 / 2$ and for cylinders parallel to the direction of flow the factor equals one [38].

### 2.4.3 The Size of the Particles

To define regular particles such as cubes, cylinders or spheres, the length, width, thickness or diameter are usually used. However it becomes difficult when the particles are irregular [38].

The particle size and vessel size are interrelated in their influence upon porosity. The presence of the container wall interrupts the pattern of particle-toparticle contacts and hence makes for a large fraction voids at the wall [5], Figure 2.7 shows the fluctuation of porosity in a bed of spheres and cylinders [39].

Distance from the wall
Figure 2.7 The Fluctuation of porosity in a bed of spheres and cylinders [39]

To decrease wall effects, the particle diameter should be small in comparison with the column diameter in which the packing is contained [40]. Furnas in 1931 [41] studied the wall effect and found that when the ratio of the diameter of the container $\left(D_{b}\right)$ to that of the particle $\left(d_{p}\right)$ is greater than 10:1, the wall effect can be neglected [39].

Carman in 1937 [46] and Coulson in 1949 [49] made no correction for the change in porosity near the wall. They used the mean porosity and for low rates added half the area of the walls to the surface area of the particles. A wall affects correction factor $f w$, for the velocity though the packed bed has been determined experimentally by Coulson [16] as:

$$
\begin{equation*}
f_{w}=\left(1+\frac{1}{2} \frac{S_{c}}{S}\right)^{2} \tag{2.13}
\end{equation*}
$$

where:
$\mathrm{S}_{\mathrm{c}}=$ is the surface area of the container per unit volume of bed.
$S=$ is the specific surface area of the particles.

### 2.4.4 The Shape of the Particles.

Particle shape is a more important variable in porosity determination than is surface roughness, though both of the variables act in the same way. The lower the particle sphericity the more open is the bed. Particles settle cross each other and packed with pointed ends against each other, preventing a close packing. Figure 2.8 shows the sphericity as a function of porosity for random-packed beds of uniformly sized particles [5].

Figure 2.8 Sphericity as a function of porosity for random-packed beds of uniformly sized particles [5].

Particle shape is the ratio of the particle property to the property a sphere having a diameter equal to the measured particle dimension. The most commonly used of the shape factors is the sphericity $\left(\emptyset_{s}\right)$. Sphericity is defined as the ratio of the surface area of this sphere to the surface area of particle [13], as shown below:

$$
\begin{equation*}
\phi_{S}=\frac{S_{\text {sphere }}}{S_{\text {particle }}}=\frac{\pi d_{p}^{2}}{S_{\text {particle }}} \tag{2.14}
\end{equation*}
$$

where:
$d_{p}$ is the diameter of a sphere of the same volume as the particle

Therefore the value of sphericity for spheres particle equal one and for other shapes is less than one [38].Table 2.1 shows the shape factor of different shape materials [43].

Table 2.1 Sphericity of different shape materials [43]

| Material | Sphericity | Material | Sphericity |
| :---: | :---: | :---: | :---: |
| Sphere, cubes, short <br> cylinders ( $\mathrm{L}=\mathrm{d}_{\mathrm{p}}$ ) <br> Rashing rings $\left(\mathrm{L}=\mathrm{d}_{\mathrm{p}}\right)$ | 1.0 | Ottawa sand | 0.95 |
|  |  | Rounded sand | 0.83 |
|  |  | Coal dust | 0.73 |
| Rashing rings$\begin{aligned} & \mathrm{L}=\mathrm{d}_{\mathrm{po}} *, \mathrm{~d}_{\mathrm{pi}}=0.5 \mathrm{~d}_{\mathrm{po}} * \\ & \mathrm{~L}=\mathrm{d}_{\mathrm{po}}, \mathrm{~d}_{\mathrm{pi}}=0.75 \mathrm{~d}_{\mathrm{po}} \end{aligned}$ | $\begin{gathered} 0.58 \\ 0.33 \\ \hline \end{gathered}$ | Flint sand | 0.65 |
|  |  | Crushed glass | 0.65 |
| Berl saddles | 0.3 | Mica flakes | 0.28 |
| * $\mathrm{d}_{\mathrm{po}}, \mathrm{d}_{\mathrm{pi}}$ is the outside and inside diameter of rashing rings. |  |  |  |

### 2.4.5 The surface roughness of the particles

Surface roughness has two major effects; it increases the resistance of the bed to fluid flow and increases the porosity of the bed [38].

The effects of surface roughness upon the pressure drop have indicated a marked effect in the turbulence range. Roughness dose not affect friction in the laminar region [8].

Roughness has an effect on the effective path and the kinematic velocity of the fluid; both terms of friction factor are subject to change. The effective path is the actual path that the fluid travels [8].

For slow flow rates, the effective path for rough and smooth particles should be approximating the same because channeling effect does not differ with the degree of roughness. For high flow rates, the rough surface has more friction therefore there is a substantial difference in the pressure drops [8].

### 2.5 Specific Surface Area

The general surface of a bed of particles can often be characterized by the specific area of the bed $\left(\mathrm{S}_{\mathrm{B}}\right)$ and the fractional voidage of the bed $(\varepsilon) . \mathrm{S}_{\mathrm{B}}$ is the surface area presented to the fluid per unit volume of bed when the particles are packed in bed. Its units are (length) ${ }^{-1}$.

S is the specific surface area of the particles and is the surface area of a particle divided by its volume. Its units are again (length) ${ }^{-1}$. Therefore for spherical particle [16, 44]:

$$
\begin{equation*}
S=\frac{\text { Surfacearea }}{\text { volume }}=\frac{\pi d_{p}^{2}}{\pi\left(d_{p}^{3} / 6\right)}=\frac{6}{d_{p}} \tag{2.15}
\end{equation*}
$$

It can be seen that S and $\mathrm{S}_{\mathrm{B}}$ are not equal due to the voidage occurring when the particles are packed in to a bed. If contact points occur between particles so that only a very small fraction of surface area is lost by overlapping, then [16, 44]:

$$
\begin{equation*}
\mathrm{S}_{\mathrm{B}}=\mathrm{S}(1-\varepsilon) \tag{2.16}
\end{equation*}
$$

For a given shape of particle $S$ increases as the particle size is reduced [45].

When mixtures of sizes are studied the value of S for sphere of mixed sizes is given by [46]:

$$
\begin{equation*}
S=6(1-\varepsilon) \sum_{i=1}^{n} \frac{x_{i}}{d_{p i}} \tag{2.17}
\end{equation*}
$$

where:
$\mathrm{X}_{\mathrm{i}}$ is the fractional weight of spherical particle.
$d_{p}$ is the diameter of spherical particle.
For beds consisting of a mixture of different particle diameters, the effective particle diameter ( $\mathrm{dp}_{\text {eff }}$ ) can be used instead of $\mathrm{d}_{\mathrm{p}}$ as [13]:

$$
\begin{equation*}
d p_{\text {eff }}=\frac{1}{\sum_{i=1}^{n} \frac{x_{i}}{d_{p i}}} \tag{2.18}
\end{equation*}
$$

### 2.6 Prediction of Voidage Distribution

The characteristics of the flow through packed bed are important in filter design and understanding of the relationship between void fraction and the flow distribution is essential. Figure 2.9 shows a typical radial voidage distribution (in a bed of 98 mm in diameter packed with 4 mm spherical beads). It has been shown that, for flow through a fixed bed of uniform particles that there is a maximum velocity approximately one particle diameter from the outer wall of the bed, which decrease sharply toward the wall and more gradually away from it. The fraction of the bed influenced by this velocity profile depends on the ratio of particle size to bed diameter [47].

Figure 2.9 Typical radial voidage distributions [47]

The voidage is found to be a minimum about half a particle diameter from the wall of the bed and then follow a dumped oscillatory function until it reaches a constant value about 5 particle diameters from the wall, where the packing is random [47].

Large randomly packed beds of uniform spheres tend to pack with an average void fraction of $39 \%$ since locally; the voidage varies from point to point. Near the wall of the containing vessel the void fraction will be larger than near the center of the bed. Immediately adjacent to the wall the void fraction approach unity and in the center of the bed a minimum voidage observed [48].

### 2.7 The Relation between depth of bed and pressure drop

From the readings of the manometers, Colson found that the differences in pressure over varying depths of the packing were obtained directly. Some results for beds of spherical particles ( $\mathrm{d}_{\mathrm{p}}=5 / 32^{\circ}$ and $5 / 16$ ), plates ( $1 / 16$ ) and cylinders $(1 / 8)$ are shown graphically in Figure 2.10. The experimental points are seen to lie on straight lines indicating a linear relation between pressure drop $(\Delta \mathrm{p})$ and depth of bed (L) [49].

Figure 2.10 Relation between depth of bed and pressure drop [49]

## Chapter Three

## Theoretical Aspects

### 3.1 Introduction

This chapter deals with proposed semi-empirical equations for modeling fluid flow through packed bed. The most important parameter in the equations is the pressure drop. The semi-empirical equations proposed can be divided into several types according to the packing system, mono size packing system, binary size packing system, ternary size packing system, quaternary size packing system and quinary size packing system.

A semi-empirical equation was proposed for each type of packing referred to a singular equation. An equation that can be used for all types of packing systems is called general equation. The shape of the singular and general equations are similar, the difference between them is in the constants used in the terms of these equations.

The second factor affecting the fluid flow through packed bed is the pore diameter. The pore diameter is included in the pressure drop equation. An empirical formula was proposed to evaluate the pore diameter for each type of packing using experimental data.

The third factor affecting on the pressure drop of fluid flow through packed bed is the tortuosity factor. The simplest expression was proposed to evaluate the tortuosity for each type of packing using experimental data.

### 3.2 Fluid Flow through Randomly Packed Columns

Many attempts have been made to obtain general expressions for pressure drop and mean velocity for flow through packing in terms of voidage and specific surface, as these quantities are often known or can be measured. Alternatively, measurement of the pressure drop, velocity, and voidage provide a convenient way of measuring the surface area of some particulate materials [16].

Considering a horizontal pipe of radius R and length L with an annulus element of thickness $\Delta \mathrm{r}$ as shown in figure 2.3 below [50]:

Figure3.1 Schematic diagrams for a pipe

The momentum balance on the increment $\Delta r$ is as follows [50]:
Rate of momentum in- Rate of momentum in+ Sum of forces acting on system= accumulation

1. Rate of momentum in across cylindrical surface $=(2 \pi r L) \tau_{r z} \mid r$
2. Rate of momentum out across cylindrical surface $=(2 \pi r L) \tau_{r 2} \mid r+\Delta r$
3. Rate of momentum in across annular surface at $\mathrm{z}=0$ is
$\left.\left(2 \pi r \Delta r u_{z}\right)\left(\rho u_{z}\right)\right|_{z=0}$
4. Rate of momentum out across annular surface at $\mathrm{z}=\mathrm{L}$ is

$$
\left.\left(2 \pi \mathrm{r} \Delta r u_{z}\right)\left(\rho u_{z}\right)\right|_{z=L}
$$

5. Pressure force acting on system $=(2 \pi r \Delta r)\left(P_{0}-P_{L}\right)$

Where $\mathrm{P}_{0}$ and $\mathrm{P}_{\mathrm{L}}$ is the fluid pressure at $\mathrm{z}=0$ and at $\mathrm{z}=\mathrm{L}$, respectively. For horizontal pipe the gravitational force is neglected.

Substitution of the above five terms into the general momentum balance equation (3.1) the resulting equation will be as follows [50]:

$$
\begin{equation*}
(2 \pi r L)\left(\tau_{\left.r\right|_{r}}-\left.\tau_{r z}\right|_{r+\Delta x}\right)+\left(2 \pi r \Delta r u_{z}\right)\left(\rho u_{z}\right)_{z=0}-\left(2 \pi r \Delta r u_{z}\right)\left(\rho u_{z}\right)_{z=L}+(2 \pi r \Delta r)\left(P_{0}-P_{L}\right)=0 \tag{3.2}
\end{equation*}
$$

Since the velocity is constant along the z - axis, the net of the momentum across the annulus is zero arranging and dividing equation (3.2) by ( $2 \pi \mathrm{~L} \Delta \mathrm{r}$ ) gives the following [51]:

$$
\begin{equation*}
\frac{d}{d r}\left(r \tau_{r z}\right)=\frac{\left(P_{0}-P_{L}\right)}{L} r \tag{3.3}
\end{equation*}
$$

Integrating equation (3.3) as follows:

$$
\begin{equation*}
\tau_{r z}=\frac{\left(P_{0}-P_{L}\right)}{2 L} r+\frac{C_{1}}{r} \tag{3.4}
\end{equation*}
$$

Using the boundary condition at $\mathrm{r}=0, \tau_{\mathrm{rz}}=0$ which leads to make the shear stress to reach infinity therefore $\mathrm{C}_{1}$ must be zero

$$
\begin{equation*}
\tau_{r z}=\frac{\left(P_{0}-P_{L}\right)}{2 L} r \tag{3.5}
\end{equation*}
$$

The shear stress is defined as follows:

$$
\begin{equation*}
\tau_{r z}=-\mu \frac{d u_{z}}{d r} \tag{3.6}
\end{equation*}
$$

Substituting equation (3.5) into (3.6) and rearranging the equation as follows:

$$
\begin{equation*}
\frac{d u_{z}}{d r}=\frac{\left(P_{0}-P_{L}\right)}{2 \mu L} r \tag{3.7}
\end{equation*}
$$

Integrating equation (3.7)

$$
\begin{equation*}
u_{z}=\frac{\left(P_{0}-P_{L}\right)}{4 \mu L} r^{2}+C_{2} \tag{3.8}
\end{equation*}
$$

By using the boundary condition at the center of the pipe at velocity zero $\left(\mathrm{u}_{\mathrm{z}}=0\right)$ and the radius at $(\mathrm{r}=\mathrm{R})$, then equation (3.8) will be as follows:

$$
\begin{equation*}
C_{2}=-\frac{\left(P_{0}-P_{L}\right)}{4 \mu L} R^{2} \tag{3.9}
\end{equation*}
$$

Substituting equation (3.9) into (3.8) and rearranging as follows:

$$
\begin{equation*}
u_{z}=\frac{\left(P_{0}-P_{L}\right)}{4 \mu L} R^{2}\left(1-\left(\frac{r}{R}\right)^{2}\right) \tag{3.10}
\end{equation*}
$$

Equation (3.10) is the velocity distribution inside pipe as a function of the radius of pipe.

The average velocity is obtained by the following expression [50] as follows:

$$
\begin{equation*}
u=\frac{\int_{0}^{2} \int_{0}^{R} r u_{z} d r d \theta}{\int_{0}^{2 \pi} \int_{0}^{R} r d r d \theta} \tag{3.11}
\end{equation*}
$$

Substitution of equation (3.10) into (3.11) and integrating gives

$$
\begin{equation*}
u=\frac{\Delta P d_{t}{ }^{2}}{32 \mu L} \tag{3.12}
\end{equation*}
$$

Rearranging equation (3.12) gives

$$
\begin{equation*}
\frac{\Delta P}{L}=\frac{32 \mu u}{d_{t}{ }^{2}} \tag{3.13}
\end{equation*}
$$

Where equation (3.13) is the Hagen-Poiseuille equation, which is a physical law concerning the voluminal laminar stationary flow of Newtonian fluid through a cylindrical tube with constant circular cross-section [52].

Considering a unit volume packed bed, the volumes occupied by the voids and the solid particles are $\varepsilon$ and $(1-\varepsilon)$ respectively, where $\boldsymbol{\varepsilon}$ is the void fraction or porosity of the bed. Let $S$ is the surface area per unit volume of the solid material in the bed. Thus the total surface area $\left(\mathrm{S}_{\mathrm{B}}\right)$ in a packed bed of unit volume is ( $1-\varepsilon$ ) $\mathrm{S}[16]$.

An equivalent pore diameter $\mathrm{d}_{\text {pore }}$ for flow through the bed can be defined as four times the cross-sectional flow area divided by the appropriate flow perimeter. For random packing, this is equal to four times the volume occupied by the fluid divided by the surface area of particles in contact with the fluid. Thus, the equivalent pore diameter is [16]:

$$
\begin{equation*}
d_{\text {pore }}=\frac{4 \varepsilon}{(1-\varepsilon) S} \tag{3.14}
\end{equation*}
$$

If the free space in the bed is assumed to consist of a series of tortuous channels, then equation (3.12) for flow through a bed may be rewritten by the substitution of the equivalent diameter [16]:

$$
\begin{equation*}
u_{1}=\frac{\Delta P}{32 \mu L}\left(\frac{16 \varepsilon^{2}}{(1-\varepsilon)^{2} S^{2}}\right) \tag{3.15}
\end{equation*}
$$

The average velocity through the pore channels $\left(u_{1}\right)$ is defined as the superficial velocity (u) divided by the porosity of the bed [22].

$$
\begin{equation*}
u_{1}=\frac{u}{\varepsilon} \tag{3.16}
\end{equation*}
$$

Substituting equation (3.16) in equation (3.15), therefore equation (3.15) will be as follows:

$$
\begin{equation*}
u=\frac{\Delta P}{2 \mu L}\left(\frac{\varepsilon^{3}}{(1-\varepsilon)^{2} S^{2}}\right) \tag{3.17}
\end{equation*}
$$

Replacing equation (3.17) by the following equations:

$$
\begin{align*}
& u=\frac{\Delta P}{K_{c} \mu L}\left(\frac{\varepsilon^{3}}{(1-\varepsilon)^{2} S^{2}}\right)  \tag{3.18}\\
& \frac{\Delta P}{L}=K_{c} \frac{(1-\varepsilon)^{2} S^{2} \mu u}{\varepsilon^{3}}  \tag{3.19}\\
& \frac{\Delta P}{L}=K_{c} \frac{(1-\varepsilon)^{2} \mu u}{\varepsilon^{3}} \frac{36}{d_{p}^{2}} \tag{3.20}
\end{align*}
$$

Where $\mathrm{K}_{\mathrm{c}}$ is Kozeny's constants and given in figure (2.3) [16].

Replacing equation (3.20) by the following equation:

$$
\begin{equation*}
\frac{\Delta p}{L}=K_{1} \frac{(1-\varepsilon)^{2} \mu u}{\varepsilon^{3} d_{p}^{2}} \tag{3.21}
\end{equation*}
$$

where $\mathrm{K}_{1}$ is a dimensionless empirical constant [6]. Equation (3.21) is known as the Carmen-Kozeny equation and has been successfully used to calculate pressure drop for laminar flow through packed bed. Carman [46] applied this equation to experimental results on flow through packed beds and found that $K_{1}=180$.

At high Reynolds number the kinetic-energy losses become significant, which was found by modifying the kinetic-energy term [5].

$$
\begin{equation*}
\frac{\Delta P}{\rho}=\frac{u_{1}^{2}}{2} \tag{3.22}
\end{equation*}
$$

If the energy loss is to occur repeatedly in a unit channel length, then equation (3.22) will be as follows:

$$
\begin{equation*}
\frac{\Delta P}{L}=\frac{n}{2} \rho u_{1}^{2} \tag{3.23}
\end{equation*}
$$

Where $\mathrm{n}=$ the number of repetitive kinetic-energy losses in a unit length $\Delta \mathrm{P}=$ pressure drop due to kinetic-energy losses

In the channels under consideration, the expansions in channel width probably occur at distance roughly equivalent to the channel diameter. This follows because the particulate bed has been replaced by a model consisting of many parallel, circular ducts. The diameter of these ducts will be proportional to the particle diameter, and the fact of one expansion occurring for each particle is thus approximated. Using n proportional to $1 / \mathrm{d}_{\mathrm{t}}$ gives [5]:

$$
\begin{equation*}
\frac{\Delta P}{L}=K \frac{\rho u_{1}^{2}}{d_{t}} \tag{3.24}
\end{equation*}
$$

Equation (3.24) must be converted in term of $d_{p}$ and $u$ by substituting the equation of specific surface area ( $\mathrm{S}=6 / \mathrm{d}_{\mathrm{p}}$ ) and the intestinal velocity from equation (3.16), therefore equation (3.24) will be as follows [5]:

$$
\begin{equation*}
\frac{\Delta P}{L}=K \frac{\frac{\rho u^{2}}{\varepsilon^{2}}}{\frac{4 \varepsilon d_{p}}{6(1-\varepsilon)}}=K_{2} \frac{\rho u^{2}}{d_{p}} \frac{(1-\varepsilon)}{\varepsilon^{3}} \tag{3.25}
\end{equation*}
$$

where $\mathrm{K}_{2}$ is a dimensionless empirical constant that through many experiments was determined to equal to 1.75 [6].This equation was first derived by Burke and Plummer [53] to express the pressure drop of turbulent flow through packed bed.

Equation (3.21) for the pressure drop caused by form drag and equation (3.25) for the pressure drop caused by kinetic-energy losses may be added to obtain the total pressure drop resulting from flow through the bed [5].

$$
\begin{equation*}
\frac{\Delta P}{L}=K_{1} \frac{(1-\varepsilon)^{2}}{\varepsilon^{3}} \frac{\mu u}{d_{p}^{2}}+K_{2} \frac{(1-\varepsilon)}{\varepsilon^{3}} \frac{\rho u^{2}}{d_{p}} \tag{3.26}
\end{equation*}
$$

Where u is the fluid velocity, $\Delta \mathrm{P}$ is the pressure drop, L is the length of the bed and $\mathrm{K}_{1}$ and $\mathrm{K}_{2}$ are factors which depend on both fluid and porous medium properties.

The expression for $\mathrm{K}_{1}$ and $\mathrm{K}_{2}$ has been studied by many investigators, the most widely used expression is that given by Ergun in 1952 [54] as shown below:

$$
\begin{equation*}
\frac{\Delta P}{L}=150 \frac{(1-\varepsilon)^{2}}{\varepsilon^{3}} \frac{\mu u}{d_{p}^{2}}+1.75 \frac{(1-\varepsilon)}{\varepsilon^{3}} \frac{\rho u^{2}}{d_{p}} \tag{3.27}
\end{equation*}
$$

Ergun equation has been modified by Duplessis in 1994 by using the pore diameter instead of particle diameter and using the tortuosity factor, then equation (3.27) will be as follows [15]:

$$
\begin{equation*}
\frac{\Delta P}{L}=36 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+2.05 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \tag{3.28}
\end{equation*}
$$

Where $\tau$ is the medium tortuosity and $\mathrm{d}_{\text {pore }}$ is the equivalent pore diameter.
A semi- empirical equation has been based on the same formula of Duplessis equation for the different types of packing systems by using experiments data from literature for water and air flow through packed bed.

The semi-empirical equation is comparable with Duplessis equation, and can be written as follows:

$$
\begin{equation*}
\frac{\Delta P}{L}=b_{1} \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+b_{2} \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \tag{3.29}
\end{equation*}
$$

where $b_{1}$ and $b_{2}$ are constants which can be evaluated from experimental data taken from literature by statistical fitting. The above equation can be used for each type of packing system by using experimental data used statistical fitting to find the constants of equation.

### 3.2 The Tortuosity Factor

The most important parameter needed to represent in this work is the tortuosity of sphere packing which is included in equation (3.29) as one of the main parameters.

The empirical equation of tortuosity can be calculated using the following equation [31]:

$$
\begin{equation*}
\tau=\sqrt{\left(1-\ln \varepsilon^{2}\right)} \tag{3.30}
\end{equation*}
$$

Equation (3.30) is one of the expressions that show the dependence of tortuosity in porosity of packed bed.

Equation (3.30) can be proposed to add more accurate empirical formula on the tortuosity in equation (3.29). The new form of the tortuosity which can be written in the following expression:

$$
\begin{equation*}
\tau=\sqrt{b_{1}-b_{2} \ln (\varepsilon)^{2}} \tag{3.31}
\end{equation*}
$$

The constants of equation (3.31) can be evaluated from experimental data taken from literatures [3, 4, 7, 8, 56, 57, 58, 59, 60, 61, and 62] by using statistical fitting.

## Chapter Four

## Results and discussion

### 4.1 The Semi-Empirical Equations Constants

Equation (3.29) in chapter three has been fitted using experimental data obtained from literatures $[3,4,7,8,56,57,58,59,60,61$, and 62] as shown in table 4.1, in order to calculate the different constant in it. This has been done for water and air flow through packed bed of different types and sizes of packing. The resulted constants are presented in tables 4.2 and 4.3.

Table 4.1 Experimental data for different types and sizes of packing

| Types of packing <br> materials | system | Particle diameter <br> $(\mathbf{c m})$ | Bed diameter <br> (cm) | Height of <br> packing (cm) |
| :--- | :--- | :--- | :--- | :--- |
| Glasses, pea gravel, <br> black marbles [3] | Water | $0.25,0.635,1.095$, <br> 1.27 | $8.89,15.24$ | $38.1,48.26$, <br> 45.72 |
| Pea gravel, glass <br> marbles [4] | Water | 1.27 | $8.89,15.24$ | 46.99 |

### 4.2 Calculation of Pore Diameter

The effective pore diameter for granular packing can be determined by using the following equation [55]:

$$
\begin{equation*}
d_{\text {pore }}=\frac{2}{3} d_{p} \frac{\varepsilon}{(1-\varepsilon)} \tag{4.1}
\end{equation*}
$$

Equation (4.1) can be modified to add more accurate formula of equation (3.29). The particle diameter and porosity of the bed were used to write a new form of pore diameter.

The calculation of pore diameter was based on analysis of experimental data taken from literatures $[3,4,7,8,56,57,58,59,60,61$, and 62]. Table 4.4 shows the diameter of pore for different sizes of packing systems.

| F. Quinary Size |  |  |  |
| 27. | 0.00231 | 0.0061 | 0.3623 |

The following steps can be considered to calculate pore diameter in packed bed:

1. Dependence on particle diameter:

It is noticed that pore diameter increases with increasing in particle diameter at constant porosity so that pore diameter was proportional with particle diameter as shown in runs (16 and 19) i.e.:

$$
\begin{equation*}
d_{\text {pore }} \alpha d_{p} \tag{4.2}
\end{equation*}
$$

The resulting equation will be as follows:

$$
\begin{equation*}
d_{\text {pore }}=k_{p} d_{p} \tag{4.3}
\end{equation*}
$$

2. Dependence on porosity of packed bed:

It is noticed that the pore diameter decreases with decreasing in porosity at constant particle diameter so that pore diameter was directly proportional with porosity as shown in runs (2 and 5), (9 and 13), (11 and 12), (14 and 27), and (17 and 18) i.e.:

$$
\begin{equation*}
d_{\text {pore }} \alpha \varepsilon \tag{4.4}
\end{equation*}
$$

The resulting equation will be as follows:

$$
\begin{equation*}
d_{\text {pore }}=k_{\varepsilon} \varepsilon \tag{4.5}
\end{equation*}
$$

Combining equations (4.5) and (4.3) gives:

$$
\begin{equation*}
d_{\text {pore }}=k_{p} k_{\varepsilon} d_{p} \varepsilon \tag{4.6}
\end{equation*}
$$

Replacing equation (4.6) by the following equation:

$$
\begin{equation*}
d_{\text {pore }}=b_{1} d_{p}^{b 2} \varepsilon^{b_{3}} \tag{4.7}
\end{equation*}
$$

where $b_{1}, b_{2}$ and $b_{3}$ are constants and can be evaluated by using statistical fitting. The Pore diameter used in equation 3.29 is taken from formula (4.7) after fitting for water and air through packed bed. The resulting constants are written in table 4.5 .
Table 4.5 Pore diameter formula constants for air and water flow through packed bed

### 4.3 The Effect of Different Parameters on the pressure drop on the proposed General Equation

This section shows the effect of different parameter on pressure drop using equation 3.29 after the substitution of the constants for the general equation multi-sized particles systems. The systems include all different types of spherical particles packing sizes namely mono, binary, ternary, quaternary and quinary.

The important parameters affecting the pressure drop in the equation was found to be porosity, pore diameter, tortuosity, and bed length.
The fluid physical properties used in all fluid flow equations were taken from experiments held at temperature of $\left(32^{\circ} \mathrm{C}\right)$ for air flow and $\left(25^{\circ} \mathrm{C}\right)$ for water flow through packed bed [43]. The physical properties (density and viscosity) are shown in table 4.6.

Table 4.6 Physical Properties of Fluids [43].

| Type of fluid | Density $\left(\mathrm{kg} / \mathrm{m}^{3}\right)$ | Viscosity $(\mathrm{kg} / \mathrm{m} . \mathrm{s})$ |
| :---: | :---: | :---: |
| Water | 995.647 | $0.8 * 10^{-3}$ |
| Air | 1.1582 | $1.88^{*} 10^{-5}$ |

### 4.3.1 Effect of Pore Diameter on Pressure Drop:

Figure 4.1 and 4.2 shows the variation of velocity on calculated pressure drop values for water and air flow through packed bed respectively. It is noticed that an increase in the pore diameter causes decrease in the pressure drop; this is due to the fact that when the pore diameter increases the resistance of fluid flow decreases which lead to decrease in pressure drop. For example for air flow through packed bed at velocity $0.28 \mathrm{~m} / \mathrm{s}$ when the pore diameter is 0.001 m the pressure drop is 117.5028 Pa , while for the same velocity with pore diameter of 0.0018 m the pressure drop is 56.9185 Pa .

Figure 4.1 Pressure drop vs. velocity at different pore diameters of particles for tortuosity of 1.43 , porosity 0.3 and bed length 0.2 m .

Figure 4.2 Pressure drop vs. velocity at different pore diameters of particles for tortuosity of 1.4 , porosity 0.3 and bed length 0.15 m .

### 4.3.2 Effect of Porosity on Pressure Drop:

Figure 4.3 and 4.4 shows the variation of velocity on calculated pressure drop values for water and air flow through packed bed respectively. It is noticed that when the porosity increases the pressure drop decreases, where the void fraction between particles become larger this leads to less resistance to fluid flow through the bed [63]. For example for water flow through packed bed at velocity $0.01 \mathrm{~m} / \mathrm{s}$ when the porosity is 0.3 the pressure drop is 1084.439 Pa , while for the same velocity with porosity of 0.32 the pressure drop is 953.1203 Pa .

Figure 4.3 Pressure drop vs. velocity at different porosities for tortuosity of 1.43, pore diameter 0.8 cm and bed length 20 m .

Figure 4.4 Pressure drop vs. velocity at different porosities for tortuosity of 1.4, pore diameter 0.1 cm and bed length 15 cm .

### 4.3.3 Effect of Packing Height on Pressure Drop:

Figure 4.5 and 4.6 shows the variation of velocity on calculated pressure drop values for water and air flow through packed bed respectively. It is noticed that whenever the length of the packing height increases the fluid flow resistance increases this leads to an increase in pressure drop, as shown by the work of Coluson 1949[49]. For example for water flow through packed bed at velocity $0.01 \mathrm{~m} / \mathrm{s}$ when the packing height is 0.2 m the pressure drop is 1084.439 , while for the same velocity with packing height of 0.3 m the pressure drop increased to 1626.659 Pa , further increase in the packing height to 0.6 m for the same velocity the pressure drop increased to 3253.317 Pa .

Figure 4.5 Pressure drop vs. velocity at different bed lengths for tortuosity of 1.43, pore diameter 0.08 cm and porosity 0.3 .

Figure 4.6 Pressure drop vs. velocity at different bed lengths for tortuosity of 1.4, pore diameter 0.1 cm and porosity 0.3 .

### 4.3.4 Effect of Tortuosity on Pressure Drop:

Figure 4.7 and 4.8 shows the variation of velocity on calculated pressure drop values for water and air flow through packed bed respectively. It is noticed that that whenever the tortuosity of the packing increases the voidage of packing decreases, which leads to increase pressure drop [31]. For example for water flow through packed bed at velocity $0.01 \mathrm{~m} / \mathrm{s}$ when the tortuosity is 1.43 the pressure drop is 1084.439 , while for the same velocity with tortuosity of 1.46 the pressure drop increased to 1182.494 Pa .

Figure 4.7 Pressure drop vs. velocity at different tortuosities for bed length 0.2 m , pore diameter 0.0008 m and porosity 0.3 .

Figure 4.8 Pressure drop vs. velocity at different tortuosities for bed length 0.15 m , pore diameter 0.001 m and porosity 0.3 .

### 4.4 Comparisons between Proposed Equation, Ergun Equation and Experimental Data.

### 4.4.1 Singular Equations Results for Different Sizes of Packing 4.4.1.1 Mono Size Spherical Particle System

## A. Air Flow Through Packed Bed

The values of pressure drop versus velocity for air flow through packed beds of mono size particles are plotted in figures 4.9 to 4.13 .

Figure 4.9 Pressure drop vs. velocity for spherical particle diameter of 0.61 cm , pore diameter of 0.27 cm , tortuosity of 1.4182 , bed porosity of 0.4005 , packing height of 15.15 cm and bed diameter of 7.62 cm [58] (Appendix A.5)

Figure 4.10 Pressure drop vs. velocity for spherical particle diameter of 0.61 cm , pore diameter of 0.27 cm , tortuosity of 1.4184 , bed porosity of 0.3998 , packing height of 15.15 cm and bed diameter of 7.62 cm [56] (Appendix A.6)

It can be noticed that the pressure drop values in figure 4.9 are range in 13.2473-98.0898 Pa which are less than those in figure 4.10 (range from $13.3468-384.429) \mathrm{Pa}$, because the porosity in figure 5.9 ( 0.4005 ) is greater than in figure 5.10 which is ( 0.3998 ), as the porosity decreased the pressure drop increases [16].

Figure 4.11 Pressure drop vs. velocity for spherical particle diameter of 0.7955 cm , pore diameter of 0.37 cm , tortuosity of 1.4157 , bed porosity of 0.4088 , packing height of 15.15 cm and bed diameter of 7.62 cm [56] (Appendix A.4)

Figure 4.12 Pressure drop vs. velocity for spherical particle diameter of 0.7955 cm , pore diameter of 0.37 cm , tortuosity of 1.4157 , bed porosity of 0.4088 , packing height of 20 cm and bed diameter of 7.62 cm [57] (Appendix A.2)

Figure 4.11 and 4.12 shows that as the packing height increased the pressure drop increased, this is because when the packing height increased the fluid flow resistance increased and this leads to an increase in the pressure drop. The packing height increased from (15.15) cm in Fig. 5.11 to 20 cm in Fig. 5.12, which led to increase the pressure drop values from the range of (7.8332257.286) Pa in Fig 5.11, to the range of (10.6549-347.817) Pa in Fig 5.12, for the same porosity of 0.4088 , bed diameter of 7.62 cm , and particle diameter of 0.7955 cm with pore diameter of 0.37 cm .

Figure 4.13 Pressure drop vs. velocity for spherical particle diameter of 0.9987 cm , pore diameter of 0.48 cm , tortuosity of 1.4129 , bed porosity of 0.4181 , packing height of 15.15 cm and bed diameter of 7.62 cm [56] (Appendix A.7)

The wall affect on the bed porosity and increase its value, this appears in Fig. 4-13 where the bed porosity increases to a value of 0.4181 this wall effect may be due to that the ratio of bed diameter $(7.62 \mathrm{~cm})$ to the particles diameter $(0.9987 \mathrm{~cm})$ is less than the supposed ratio $\left(\frac{D}{d_{p}} \geq 10\right)[41]$.

The best fitting for the experimental data for mono size systems for spherical particles are represented by the following equation.

$$
\begin{equation*}
\frac{\Delta P}{L}=48.49076 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+2.220827 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \tag{4.9}
\end{equation*}
$$

The average percentage error was found $7.25509 \%$ between experimental work and the proposed equation.

## B. Water Flow Through Packed Bed

The values of pressure drop versus velocity for water flow through packed beds of mono size particles were plotted in figures 4.14 to 4.17

Figure 4.14 Pressure drop vs. velocity for spherical particle diameter of 0.64 cm , pore diameter of 0.24 cm , tortuosity of 1.4309 , bed porosity of 0.3609 , bed diameter of 8.883 cm and packing height of 45.72 cm [3] (Appendix B.4)

Figure 4.15 Pressure drop vs. velocity for spherical particle diameter of 1.27 cm , pore diameter of 0.57 cm , tortuosity of 1.4172 , bed porosity of 0.4037 , bed diameter of 8.883 cm and packing height of 45.72 cm [3] (Appendix B.8)

It can noticed that in Figure 4.14 and 4.15 show that as the pore diameter decreased from 0.57 cm in fig. 4.15 to 0.24 cm in fig. 4.14 , the bed porosity will decrease from 0.4037 to 0.3609 , which led to increase the pressure drop values from the range of (45.6247-1400.02) Pa (fig.4.15) to the range of (246.84295183.159) Pa (fig.4.14), this is because when the porosity decreased the fluid flow resistance increased this is leads to an increase in pressure drop for the same bed diameter of 8.883 cm and packing height of 45.72 cm .

Figure 4.16 Pressure drop vs. velocity for black marble diameter of 1.27 cm , pore diameter of 0.57 cm , tortuosity of 1.4183 , bed porosity of 0.4 , packing height of 46.99 cm and bed diameter of 8.89 cm [4] (Appendix B.7)

Figure 4.17 Pressure drop vs. velocity for spherical particle diameter of 1.27 cm , pore diameter of 0.57 cm , tortuosity of 1.4172 , bed porosity of 0.4 , packing height of 45.72 cm and bed diameter of 8.89 cm [3] (Appendix B.8)

Figure 4.16 show that the proposed model results of pressure drop-velocity curve is close to the values of experimental results curve. The values of pressure drop of the model results in fig. 4.16 (range from 87.8937-3330.22) Pa are close to those of experimental data results (range from $74.658-3807.558$ ) Pa , for velocity (range from $0.0131-0.0996$ ) $\mathrm{m} / \mathrm{s}$. This means that the proposed equation is very close to the experimental results.

The best fitting for the experimental data for mono size systems for spherical particles are represented by the following equation:

$$
\begin{equation*}
\frac{\Delta P}{L}=54.38942 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+1.5889 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \tag{4.10}
\end{equation*}
$$

The average percentage error was found $11.0591 \%$ between experimental work and the proposed equation.

### 4.4.1.2 Binary Sizes Spherical Particle System

## A. Air Flow Through Packed Bed

The values of pressure drop versus velocity for air flow through packed beds of binary sized spherical particles were plotted in figures 4.18 to 4.20

Figure 4.18 Pressure drop vs. velocity for spherical particle diameters of $\left(\mathrm{dp}_{1}=0.79\right.$, $\mathrm{dp}_{2}=1.01, \mathrm{dp}_{\text {eff }}=0.89 \mathrm{~cm}$ ), pore diameter of 0.37 cm , tortuosity of 1.3990 , bed porosity is 0.3832 , bed diameter is 7.64 cm and packing height is 20 cm [57] (Appendix A.9)

Figure 4.19 Pressure drop vs. velocity for spherical particle diameters of ( $\mathrm{dp} 1=0.9987$ and $\mathrm{dp} 2=0.7955 \mathrm{~cm}$, with $\mathrm{dp}_{\text {eff }}=0.886 \mathrm{~cm}$ ), fraction of $\left(\mathrm{x}_{1}=0.5, \mathrm{x}_{2}=0.5\right)$, pore diameter of 0.41 cm , tortuosity of 1.3992 , bed porosity of 0.4079 , bed diameter is 7.64 cm and packing height is 15.15 cm [56] (Appendix A.10)

Figure 4.20 Pressure drop vs. velocity for spherical particle diameters of $\left(\mathrm{dp}_{1}=0.9987\right.$, $\mathrm{dp}_{2}=0.6015, \mathrm{dp}_{\text {eff }}=0.7508 \mathrm{~cm}$ ), pore diameter of 0.33 cm , tortuosity of 1.3947 , bed porosity is 0.3986 , bed diameter is 7.64 cm and packing height is 15.15 cm [56]
(Appendix A.8)

Figure 4.19 and 4.20 show that as pore diameter decreased from 0.41 cm (fig.4.19) to 0.33 cm (fig.4.20), the bed porosity decreased from 0.4079 to 0.3986, which led to increase the pressure drop values from the range of (5.0892187.56) Pa (fig.4.19) to the range of $(7.3059-248.659) \mathrm{Pa}$ (fig.4.20), this is because when the porosity decreased this leads to an increase in pressure drop for the same bed diameter of 7.64 cm and packing height of 15.15 cm .

The best fitting for the experimental data for binary size systems for spherical particles are represented by the following equation:

$$
\begin{equation*}
\frac{\Delta P}{L}=36.06787 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+2.0205 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \tag{4.11}
\end{equation*}
$$

The average percentage error was found $9.9593 \%$ between experimental work and the proposed equation.

## B. Water Flow through Packed Bed

The values of pressure drop versus velocity for water flow through packed beds of binary sized spherical particles were plotted in figures 4.21 and 4.22

Figure 4.21 Pressure drop vs. velocity for Acrylic balls of particles diameters ( $\mathrm{dp} 1=0.636$ and $\mathrm{dp} 2=1.27 \mathrm{~cm}$, with $\mathrm{dp}_{\text {eff }}=0.907 \mathrm{~cm}$ ), fraction of ( $\mathrm{x}_{1}=0.4, \mathrm{x}_{2}=0.6$ ), pore diameter of 0.35 cm , tortuosity of 1.4044 , bed porosity of 0.3645 , packing height of 48.26 cm and bed diameter of 8 cm [61](Appendix B.15)

Figure 4.22 Pressure drop vs. velocity for Acrylic balls of particles diameters $\left(\mathrm{dp} 1=0.636\right.$ and $\mathrm{dp} 2=1.27 \mathrm{~cm}$, with $\left.\mathrm{dp}_{\mathrm{eff}}=0.7065 \mathrm{~cm}\right)$, fraction of $\left(\mathrm{x}_{1}=0.8, \mathrm{x}_{2}=0.2\right)$, pore diameter of 0.27 cm , tortuosity of 1.4055 , bed porosity of 0.3609 , packing height of 48.26 cm and bed diameter of 8 cm [61](Appendix B.14)

Figure 4.22 show that the value of porosity (0.3609) is less than in fig. 4.21 (0.3645), this is due to that the weight fraction of small particles in fig. 4.22 (0.8) is less than it in figure $4.21(0.4)$, this is because in binary system the particles with smaller sizes tend to fill the voids between the larger sizes particles. [56]

The best fitting for the experimental data for binary size systems for spherical particles are represented by the following equation:

$$
\frac{\Delta P}{L}=148.8836 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+0.8343 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}}
$$

The average percentage error was found $12.6548 \%$ between experimental work and the proposed equation.

### 4.4.1.3 Ternary Sized Spherical Particle System

## A. Air Flow Through Packed Bed

The values of pressure drop versus velocity for air flow through packed beds of ternary sized spherical particles were plotted in figures 4.23 to 4.26

Figure 4.23 Pressure drop vs. velocity for spherical particles diameters of ( 0.9987 , 0.7955 and 0.509 cm , with $\mathrm{dp}_{\text {eff }}=0.7104 \mathrm{~cm}$ ), pore diameter of 0.29 cm , tortuosity of 1.4525 , bed porosity of 0.3796 , packing height of 15.15 cm and bed diameter of 7.64 cm [56] (Appendix A.15)

Figure 4.24 Pressure drop vs. velocity for spherical particles diameters of ( $0.24,0.42$ and 0.82 cm , with $\mathrm{dp}_{\text {eff }}=0.3862 \mathrm{~cm}$ ), pore diameter of 0.13 cm , tortuosity of 1.5014 , bed porosity of 0.3428 , packing height of 15.15 cm , bed diameter of 7.64 cm [58] (Appendix A.12)

Figure 4.25 Pressure drop vs. velocity for spherical particles diameters of ( $0.9987,0.7955$ and 0.6015 cm , with $\mathrm{dp}_{\mathrm{eff}}=0.7651 \mathrm{~cm}$ ), pore diameter of 0.35 cm , tortuosity of 1.4156 , bed porosity of 0.3899 , packing height of 15.15 cm and bed diameter of 7.64 cm [56]
(Appendix A.13)

The above figures show that tortuosity increased from 1.4156 cm (fig.4.25) to the 1.5014 cm (fig.4.24), the bed porosity decreased from 0.3899 to 0.3428 , which led to increase the pressure drop values from the (range of 7.8542 -231.42 ) Pa (fig.4.25) to (the range of (13.2949-697.8937) Pa (fig.4.24), as tortuosity of porous and granular media increased the void fraction of packed bed will be decrease, this is leads to increase in pressure drop for the same bed diameter of 7.64 cm and packing height of 15.15 cm [31].

Figure 4.26 Pressure drop vs. velocity for spherical particles diameters of ( 0.9987 , 0.7955 and 0.6015 cm , with $\mathrm{dp}_{\text {eff }}=0.7651 \mathrm{~cm}$ ), pore diameter of 0.35 cm , tortuosity of 1.4156 , bed porosity of 0.405 , packing height of 15.15 cm and bed diameter of 7.64 cm [56] (Appendix A.14)

Figure 4.27 Pressure drop vs. velocity for spherical particle diameters of (dp1=0.9987 and $\mathrm{dp} 2=0.7955 \mathrm{~cm}$, with $\left.\mathrm{dp}_{\mathrm{eff}}=0.886 \mathrm{~cm}\right)$, fraction of $\left(\mathrm{x}_{1}=0.5, \mathrm{x}_{2}=0.5\right)$, pore diameter of 0.41 cm , tortuosity of 1.3992 , bed porosity of 0.4079 , bed diameter of 7.64 cm and packing height of 15.15 cm [56] (Appendix A.10)

The porosity highly affects the pressure drop and inversely proportional to it [66]; this is appeared in figure 4.26 and 4.27. This figure shows that the bed porosity decreased from 0.4079 in fig. 4.27 to 0.405 in fig. 4.26 , which led to increase the pressure drop values from the range of $(5.0892-187.5597) \mathrm{Pa}$ in binary size particles (fig.4.27) to the range of (7.8542-231.42) Pa in ternary size particles (fig.4.26) for the same bed diameter of 7.64 cm and packing height of 15.15 cm .

The best fitting for the experimental data for ternary size systems for spherical particles are represented by the following equation:

$$
\begin{equation*}
\frac{\Delta P}{L}=49.91447 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+1.85297 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \tag{4.13}
\end{equation*}
$$

The average percentage error was found $12.9554 \%$ between experimental work and the proposed equation.

## B. Water Flow Through Packed Bed

The values of pressure drop versus velocity for water flow through packed beds of ternary size particles were plotted in figures 4.28 and 4.29

Figure 4.28 Pressure drop vs. velocity for spherical particles diameter of ( 0.9987 , 0.7955 and 0.421 , with $\mathrm{dp}_{\text {eff }}=0.6477 \mathrm{~cm}$ ), pore diameter of 0.28 cm , tortuosity of 1.4366 , bed porosity of 0.3921 , packing height of 15.15 cm and bed diameter of 7.62 cm [56](Appendix B.26)

Figure 4.29 Pressure drop vs. velocity for spherical particles diameter of ( $0.51,0.79$ and 1.01 , with $\mathrm{dp}_{\text {eff }}=0.6536 \mathrm{~cm}$ ), pore diameter of 0.28 cm , tortuosity of 1.4373 , bed porosity of 0.392 , packing height of 20 cm and bed diameter of 7.62 cm [57](Appendix B.24)

Figure 4.28 shows that the proposed model results of pressure dropvelocity curve lay on the experimental results curve. The values of pressure drop of the model results in fig. 4.28 (range from $402.7382-26086.89$ ) Pa are close to those of experimental data results (range from $390.071-25886.5$ ) Pa , for the same velocity (range from $0.0303-0.303$ ) $\mathrm{m} / \mathrm{s}$. This means that the proposed model is very close to the experimental results.

The best fitting for the experimental data for ternary size systems for spherical particles are represented by the following equation:

$$
\begin{equation*}
\frac{\Delta P}{L}=65.24735 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+1.88032 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \tag{4.14}
\end{equation*}
$$

The average percentage error was found $10.5479 \%$ between experimental work and the proposed equation.

### 4.4.1.4 Quaternary Sized Spherical Particle System

## A. Air Flow Through Packed Bed

The values of pressure drop versus velocity for air flow through packed beds of quaternary size particles were plotted in figures 4.30 and 4.31

Figure 4.30 Pressure drop vs. velocity for spherical particles diameters of ( $0.42,0.51$, 0.61 and 0.79 cm , with $\mathrm{dp}_{\text {eff }}=0.552 \mathrm{~cm}$ ), pore diameter of 0.22 cm , tortuosity of 1.4862 , bed porosity of 0.371 , packing height of 20 cm and bed diameter of 7.62 cm [57] (Appendix A.18)

Figure 4.31 Pressure drop vs. velocity for spherical particles diameters of $(0.42,0.51,0.61$ and 0.79 cm , with $\mathrm{dp}_{\text {eff }}=0.5738 \mathrm{~cm}$ ), pore diameter of 0.23 cm , tortuosity of 1.4807 , bed porosity of 0.3745 , packing height of 20 cm and bed diameter of 7.62 cm [57] (Appendix A.17)

The best fitting for the experimental data for ternary size systems for spherical particles are represented by the following equation:

$$
\begin{equation*}
\frac{\Delta P}{L}=8.77095 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+2.6576 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \tag{4.15}
\end{equation*}
$$

The average percentage error was found $8.88463 \%$ between experimental work and the proposed equation.

## B. Water Flow Through Packed Bed

The values of pressure drop versus velocity for water flow through packed beds of quaternary size particles were plotted in figure 4.32

Figure 4.32 Pressure drop vs. velocity for glass spherical diameter of $(0.42,0.51,0.61$ and 0.79 , with $\mathrm{dp}_{\text {eff }}=0.55 \mathrm{~cm}$ ), pore diameter of 0.22 cm , tortuosity of 1.4861 , bed porosity of 0.3711 , packing height of 15.15 cm and bed diameter of 7.62 cm [57]
(Appendix B.30)

Figure 4.33 Pressure drop vs. velocity for spherical particles diameter of ( $0.61,0.79$ and 1.01 cm , with $\mathrm{dp}_{\text {eff }}=0.54 \mathrm{~cm}$ ), pore diameter of 0.21 cm , tortuosity of 1.4630 , bed porosity of 0.3715 , packing height of 20 cm and bed diameter of 7.62 cm [57] (Appendix B.21)

Figures 4.32 and 4.33 shows that the pressure drop increased with increased in packing height. The packing height increased from 15.15 cm (Fig. 4.32 ) to 20 cm (Fig. 4.33), which led to increase the pressure drop values from the range of (625.8377-59110.91) Pa (Fig 4.32), to the range of (970.0841$57264.93) \mathrm{Pa}$ (Fig 4.33), for the approximately near value of porosity is 0.3711 in quaternary size particles figure 4.30 and 0.3715 in ternary size particles figure 4.31 for same bed diameter of 7.62 cm and pore diameter of 0.28 cm .

The best fitting for the experimental data for quaternary size systems for spherical particles are represented by the following equation:

$$
\begin{equation*}
\frac{\Delta P}{L}=7.0890 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+2.6040 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \tag{4.16}
\end{equation*}
$$

The average percentage error was found $8.17105 \%$ between experimental work and the proposed equation.

### 4.4.1.5 Quinary Sized Spherical Particle System

## A. Air Flow Through Packed Bed

The values of pressure drop versus velocity for air flow through packed beds of quinary size particles were plotted in figure 4.34

Figure 4.34 Pressure drop vs. velocity for spherical particles diameters of ( $0.42,0.51$, $0.61,0.79$ and 1.01 cm , with $\mathrm{dp}_{\mathrm{eff}}=0.607 \mathrm{~cm}$ ), pore diameter of 0.24 cm , tortuosity of 1.509 , bed porosity of 0.3694 , packing height of 20 cm and bed diameter of 7.62 cm [57] (AppendixA.20)

Figure 4.35 Pressure drop vs. velocity for spherical particle diameter of 0.61 cm , pore diameter of 0.27 cm , tortuosity of 1.4184 , bed porosity of 0.3998 , packing height of 20 cm and bed diameter of 7.62 cm [57] (AppendixA.3)

It can be noticed that the pressure drop values in figure 4.35 mono size particles (range from 17.8431-402.292) Pa are less than those in figure 4.34 quinary size particles (range from $13.602-665.655$ ) Pa , this is because that porosity in figure 4.35 (0.3998) with pore diameter (0.27) cm is greater than in figure $4.34(0.3694)$ with pore diameter $(0.24) \mathrm{cm}$, as the porosity decreased the pressure drop will be increase.

The best fitting for the experimental data for quinary size systems for spherical particles are represented by the following equation:

$$
\begin{equation*}
\frac{\Delta P}{L}=0.06354 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+2.5551 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \tag{4.17}
\end{equation*}
$$

The average percentage error was found $12.8196 \%$ between experimental work and the proposed equation.

## B. Water Flow Through Packed Bed

The values of pressure drop versus velocity for water flow through packed beds of quinary size particles were plotted in figure 4.36

Figure 4.36 Pressure drop vs. velocity for spherical particles diameter diameter of ( $0.42,0.51,0.61,0.79$ and 1.01 cm , with $\mathrm{dp}_{\text {eff }}=0.61 \mathrm{~cm}$ ), pore diameter of 0.24 cm , tortuosity of 1.4956 , bed porosity of 0.3623 , packing height of 15.15 cm and bed diameter of 7.62 cm [57] (Appendix B.31)

It can be noticed from the above figure that the proposed equation gave good fitting to the experiment rather than Ergun equation, while the results of Ergun lies above them; this is due to the differences in beds dimensions, packing shapes and sizes used by Ergun [16].

The best fitting for the experimental data for quinary size systems for spherical particles are represented by the following equation:

$$
\begin{equation*}
\frac{\Delta P}{L}=108.3983 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+2.1188 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \tag{4.18}
\end{equation*}
$$

The average percentage error was found $4.24209 \%$ between experimental work and the proposed equation

### 4.4.2 Results of General Equation for Different Sizes of Packing Systems

## A. Air Flow Through Packed Bed

The results of the general equation are presented in this section. This presentation takes into account a comparison with Ergun equation and experimental data. The results of the general equation include mono, binary, ternary, quaternary and quinary spherical particles sizes.

The values of pressure drop versus velocity for air flow through packed beds were plotted in Fig. 4.37 for mono spherical particles, Fig. 4.38 for binary spherical particles, Fig. 4.39 for ternary spherical particles, Fig. 4.40 for quaternary spherical particles and Fig. 4.41 for quinary spherical particles systems.

Figure 4.37 Pressure drop vs. velocity for spherical particles diameter of 0.7955 cm , pore diameter of 0.37 cm , tortuosity of 1.4312 , bed porosity of 0.4088 , packing height of 15.15 cm and bed diameter of 7.62 cm [56]

Figure 4.38 Pressure drop vs. velocity for spherical particle diameters of (dp1=0.9987 and $\mathrm{dp} 2=0.7955 \mathrm{~cm}$, with $\left.\mathrm{dp}_{\text {eff }}=0.886 \mathrm{~cm}\right)$, fraction of $\left(\mathrm{x}_{1}=0.5, \mathrm{x}_{2}=0.5\right)$, pore diameter of 0.41 cm , tortuosity of 1.4314 , bed porosity of 0.4079 , bed diameter of 7.64 cm and packing height of 15.15 cm [56]

Figure 4.39 Pressure drop vs. velocity for spherical particles diameters of ( $0.9987,0.7955$ and 0.6015 cm , with $\mathrm{dp}_{\text {eff }}=0.7651 \mathrm{~cm}$ ), pore diameter of 0.35 , tortuosity of $1.4311, \mathrm{~cm}$, bed porosity of 0.3899 , packing height of 15.15 cm and bed diameter of 7.64 cm [56]

Figure 4.40 Pressure drop vs. velocity for spherical particles diameters of $(0.42,0.61,0.79$ and 1.01 cm , with $\mathrm{dp}_{\text {eff }}=0.6373 \mathrm{~cm}$ ), pore diameter of 0.27 cm , tortuosity of 1.4366 , bed porosity of 0.3843 , packing height of 20 cm and bed diameter of 7.62 cm [57]

Figure 4.41 Pressure drop vs. velocity for spherical particles diameters of ( $0.24,0.51$, $0.61,0.79$ and 1.01 cm , with $\mathrm{dp}_{\text {eff }}=0.607 \mathrm{~cm}$ ), pore diameter of 0.24 cm , tortuosity 1.4401, bed porosity of 0.3694 , packing height of 20 cm and bed diameter of

$$
7.62 \mathrm{~cm}[57]
$$

The proposed equation (3.29) was fitted for air flow through packed beds of multi sized particles, so the general form of the proposed equation for air flow through packed beds will be as follows:

$$
\begin{equation*}
\frac{\Delta P}{L}=-5.47872 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+2.7267 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \tag{4.19}
\end{equation*}
$$

The average percentage errors were found $13.57423 \%$ between experimental work and the proposed equation.

Equation 4.19 shown above can be used for all types of packing systems.
It could be noticed from figures ( 4.37 to 4.41 ) that the proposed equation gave a good fitting to the experimental results. This is due to that Ergun designed his equation using completely different procedures than experimental data work, so it was no surprise when its failure was confirmed. Ergun used pea gravel for the packed bed and air for the fluid; while the experiments were glass is used for the packed bed and air for the fluid [63]. So there is a cretin deviation between Ergun results and experimental results. This deviation was also found between the proposed equation results and the Ergun equation.

The general equation can be used for any system of packing, while the singular equation for only one types of packing, and can not be used for another type. Figures ( 4.37 to 4.41 ) show the results of the general equation for multi sized particles.

## B. For Water Flow Through Packed Bed

The following presentation of results and comparisons are based on general equation fittings for all systems considered in the present work. This system considered includes mono spherical particles, binary spherical particles, ternary spherical particles, quaternary spherical particles and multi-sizes of spherical particles systems.

The proposed equation (3.29) was fitted for water flow through packed beds of multi-sized spherical particles, so the general form of the proposed equation for water flow through packed bed will be as follows:

$$
\begin{equation*}
\frac{\Delta P}{L}=108.3983 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+2.1188 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \tag{4.20}
\end{equation*}
$$

The average percentage error was found $12.9576 \%$ between the experimental work and the proposed equation.

The values of pressure drop versus velocity for water flow through packed beds were plotted in Fig. 4.42 for mono spherical particles, Fig. 4.43 for binary spherical particles, Fig. 4.44 for ternary spherical particles, Fig. 4.45 for quaternary spherical particles and Fig. 4.46 for quinary spherical particles sizes.

Figure 4.42 Pressure drop vs. velocity for pea gravel of particles diameter 0.25 cm , pore diameter of 0.8 cm , tortuosity of 1.4506 , bed porosity of 0.360902 and packing height of 8.89 cm [3]

Figure 4.43 Pressure drop vs. velocity for Acrylic balls of particles diameter(dp1=0.636 and $\mathrm{dp} 2=1.72 \mathrm{~cm}$, with $\left.\mathrm{dp}_{\text {eff }}=0.7257 \mathrm{~cm}\right)$, fraction of $\left(\mathrm{x}_{1}=0.75, \mathrm{x}_{2}=0.25\right)$, with pore diameter of 0.27 cm , tortuosity of 1.4421 , bed porosity of 0.3612 , packing height of 50.8 cm and bed diameter of 8 cm [62]

Figure 4.44 Pressure drop vs. velocity for spherical particles diameter ( $0.9987,0.7955$ and 0.509 cm , with $\mathrm{dp}_{\text {eff }}=0.647 \mathrm{~cm}$ ), pore diameter of 0.28 cm , tortuosity of 1.4349 , bed porosity of 0.3921 , packing height of 15.15 cm and bed diameter of 7.62 cm [56]

Figure 4.45 Pressure drop vs. velocity for spherical particles diameter of $(0.42,0.51,0.61$ and 1.01 cm , , with $\mathrm{dp}_{\mathrm{eff}}=0.5738 \mathrm{~cm}$ ), pore diameter of 0.23 cm , tortuosity of 1.4395 , bed porosity of 0.3719 , packing height of 15.15 cm and bed diameter of 7.62 cm [57]

Figure 4.46 Pressure drop vs. velocity for spherical particles diameter of $(0.42,0.51,0.61$, 0.79 and 1.01 cm , with $\mathrm{dp}_{\text {eff }}=0.61 \mathrm{~cm}$ ), pore diameter of 0.23 cm , tortuosity of 1.4418 , bed porosity of 0.3623 , packing height of 15.15 cm and bed diameter of 7.62 cm [57]

It can be noticed from figures ( 4.41 to 4.46 ) that the proposed equation gave a good fitting to the experiment. The proposed equation results of pressure drop-velocity curves are close to the experimental results curves; this may be due to:

1. The difference of bed dimensions (diameter and height of bed) [68].
2. The difference of void fraction (difference of packing shape and size) [12].
3. Other reasons of this large deviation from Ergun equation, that Ergun's equation does not take in to consideration wall effects, because Ergun considered that in to packed beds it is generally assumed that the diameter of the packing is close to that of the column; therefore, there are no wall effects [59].

## Chapter Five

## Conclusions and Recommendations for Future Work

### 5.1 Conclusions

1. The proposed equations describe the effects of different parameters on pressure drop of fluid flow through packed beds, such that fluid velocity, height of packing, type of packing particles, pore size, bed porosity, tortuosity and bed diameter, compared with the experimental results.
2. Pore diameter formulas have been written for all equations used in the calculation. These formulas depend mainly on porosity and particle diameter of the bed. The calculated results of these formulas had been compared with experimental results taken from documented literature data; the comparisons show that the pore diameter formula deviate's for water flow through packed bed with small average percentage error of $0.328 \%$, and for air flow through packed bed with percentages of average errors $0.3897 \%$.
3. The tortuosity of porous media increased with decreased in porosity of packed bed, this leads to increase in pressure drop.
4. It was found that proposed equations is very close to experimental results rather than Ergun equation; this is due to the difference of bed dimensions (diameter and height of bed), the difference of void fraction (difference of
packing shape and size) and other reasons of this large deviation from Ergun equation, that Ergun's equation does not take in to consideration wall effects, because Ergun considered that in to packed beds it is generally assumed that the diameter of the packing is close to that of the column; therefore, there are no wall effects.

### 5.2 Recommendations for Future Work

The following suggestions could be considered for future work:

1. The proposed equation can be extended to include non spherical particles systems.
2. Study the flow of two phases through the packed bed.
3. Studying the effect of the surface roughness of the material on sphericity and its effects on the pressure drop of fluid flow through packed bed.

## A.1.2 Binary Sized Spherical Particles System

In the binary system, the mixture contains two sizes of spherical particles. The most noticeable effect from mixing two sizes of particles is the decrease in porosity with respect to mono size mixture.

Table A. 8 Calculation of pressure drop for spherical particles diameters of $\left(\mathrm{dp}_{1}=0.9987, \mathrm{dp}_{2}=0.6015, \mathrm{dp}_{\mathrm{eff}}=0.7508 \mathrm{~cm}\right)$, pore diameter of 0.33 cm , tortuosity of 1.3947 , bed porosity of 0.3986 , bed diameter is 7.64 cm and packing height of 15.15 cm [56]

## A.1.5 Quinary Sized Spherical Particles System

In the packing of quinary sized particles, the mixture contains five sizes of spherical particles. The percentage of each size is equal $1 / 5$ from the total packing.

Table A.19 Calculation of pressure drop for spherical particles diameters of ( 0.24 , $0.42,0.82,0.61$ and 1.03 cm , with $\mathrm{dp}_{\mathrm{eff}}=0.4818 \mathrm{~cm}$ ), pore diameter of 1.28 cm , tortuosity of 1.3521 , bed porosity of 0.2977 , packing height of 15.15 cm and bed diameter of 7.64 cm [58]

## A. 2 Results of General Equation for Different Sizes of Packing Systems

The following results are for the general equation for all systems considered in the present work. The general equation constants are shown in Tables A. 21 to A. 25 below represent the results of pressure drop through packed bed using the general equation for mono sizes spherical particles, binary sized spherical particles, ternary sized spherical particles, quaternary sized spherical particles and multi sized spherical particles respectively.

Table A.21 Calculation of pressure drop for spherical particle diameter of 1.01 cm , pore diameter of 0.48 cm , tortuosity of 1.4291 , bed porosity of 0.4186 , packing height of 20 cm and bed diameter of 7.62 cm [57]

## الخلاصة

تـم صـياغة معــدالات شـبه عمليـة لجريــن الموائـع خـلال عمـود حشوي بالاعتمـاد علـى التركيـب الاحصائي للنتنائج العطليه. تم استخدام نوعان من الموائع (الماء و الهواء) بشكل منفصل في كل مرة (جريـن طور واحد). تم استخدم عده حجوم من الحشوات، وتم دراسة كل واحد منها بشكل منفصل. تم دراسة العوامل المختلفة التي تؤثر على هبوط الضغط عند جريـان الموائع في عمود حشوي كل على حده، هذه العوامل هي سرعة جريـن الموائع، مسامية الحشوة، قطر العمود الحشوي،قطر الفتحـه في العمود الحشوي، طول الحشوة في العمود الحشوي، الالتو ائيه في العمود الحشوي و طول الحشوة في العمود الحشوي.
تم افتـر اض معادلـة شبه عمليـة لجريـان الموائـع لكل نـو ع محدد مـن الحشوات الـستنخدمة وتسمى بالمعادلــة المنفردة (احاديـه، ثنائيـه، ثالثيـة، رباعيــة، خماسـية و حشوة متعـددةالحجوم). وقـد كتبـت عشرة معادلات احادية، خمسه منها لجريان الماء وخمسة منها لجريان الهواء خلال العمود الحشوي. كمـا تم افتر اض معادلـة عامـة لجريـن المو ائع خـلال العمود الحشوي تصلح لكافـة انواع الحشوات

1. لجريان الهواءخلال العمود الحشوي

\begin{array}{r}
\frac{\Delta P}{L}=108.3983 \frac{\tau(\tau-1)^{2}}{\varepsilon^{2}} \frac{\mu u}{d_{\text {pore }}^{2}}+ \\
2.1188 \frac{\tau(\tau-1)}{\varepsilon^{2}(3-\tau)} \frac{\rho u^{2}}{d_{\text {pore }}} \\
.12 .9576 \% \text { بنسبة الخطأ }
\end{array}
$$

تم اقتراح صيغه التجريبية لحساب قطر الفتحـه وقد استخدمت لكافة معـادلات الجريـان، وتم مفارنـه نتائج الحسابات لهذه الطريقه مع نتائج التجارب الماخوذه من الجداول الموثقهه وكانت المعادلـه العامـه لحسـاب قطر الفتحه للماء والهواء هي:

$$
d_{\text {pore }}=1.9612 d_{p} \varepsilon^{1.61605}
$$

تم ايجاد نسبة الخطأ لجريان الهواء 0.3897\% ولجريان الماء 0.328\%.

## شكر وتقّقير

في البدايـة اشكر اله عز وجل الذي وفقني لاكمـال متطلبـات هذا البحث. وانـا انهي بحثي لا يسعني واعتر افا بالفضل الا ان اتقدم بو افر الشكر والامتتـان للاستاذ المشرف الدكتور محمد نصيف لطيف لاقتر احه موضوع الرسالة واشر افه عليهـا ولمو اصـلته ومتابعتـه العلميـة للبحث ومـا نرتب على ذلك من توجيهات قيمه واراء سديدة.

كمـا اتقدم بجزيـل الـشكر الـى رئـيس قسم الهندسـة الكيمياويـة، و جميع اسـاتذة قسم الهندسـة الكيمياوية لمساعدتهم القيمة لي طيلة فترة الدر اسةُ ولمدهم يد العون لي خلال اعداد هذه الرسالة. و اتقدم بشكري وامتتاني الى عمادة كليه الهندسه في جامعة النهرين،لمساعدتهم ودعمهم الدائم لي طيلة فترة الدراسة. كمـا اتقدم بالـشكر الجزيـل الـى كافـة العـاملين في المكتبـة المركزيـة بجامعـة النهرين، وذلـك

لمساعدتهم لي في الحصول على بعض المصادر المستععلة في البحث. وشكري الجزيـل الـى جميع زملائـي و زميلاتـي الذين مدو يـد العون عند حـــتي اليهـا فـي البحث.

ولا انسى ان اتقام بجزيل الشكر والتقدير الـى مـن سـاندني وسـاعدني على تخطـي الصعوبات خلال فترة البحث اللى الذين لا مثيل لهم في الدنيا الى أبي وأمي الأعزاء، أخوتي وأخواتي.

## مروة ناظم عباس

حساب انخفاض الضعظ خلا العمود الحشوي
لنظام الماء و الههو اء

رسالة
مقدمة إلى كلية اللهندسة في جامعة نهرين وهي جزء من منطلبات نيل درجة مـاجستير علوم في الهندسة الكيمياوية
